

Doing a mesoscale re-analysis using the WRF-model

Does it matter for the resulting **icing climatology**
which version of WRF you use?

Hans Bergström & Gunnar Bergström
Department of Earth Sciences, Uppsala University

Background

Previous results from the Vindforsk project V313 'Wind Power in Cold Climate' showed large differences between:

- Different models – WRF, AROME, COAMPS
- Different WRF schemes regarding:
 - Turbulence closure
 - Cloud physics
 - Large scale weather forcing

Here the WRF model has been used to further investigate these differences.

This was made using WRF-model runs with:

- **3 turbulence schemes** – (MYJ, MYNN, YSU)
- **2 cloud physics schemes** – (Thomson, WSM5/WSM6)
- **3 weather forcing sources**
 - FNL – final analysis from GFS (NOAA)
 - NNRP – NCEP-NCAR reanalysis project
 - ERA Interim – ECMWF reanalysis

From WRF-model results, icing was calculated using Makkonen's equation:

$$\frac{dM}{dt} = E \cdot w \cdot U \cdot D - Q$$

dM/dt – ice growth on a cylinder (kg/s)

M – mass (kg), t – time (s)

E - collection efficiency

w - liquid water content (kg/m^3)

U - wind speed (m/s)

D - diameter of accreted ice (m)

Q - melting or sublimation (kg/s)

Following the ISO standard for measuring ice accretion

$D = 0.03$ m. (ISO 12494 – Atmospheric icing of structures)

In reality: The diameter D will grow as ice load grows, and it is difficult to model fall-off of ice.

An option is to keep the diameter D at 0.03 m.

The resulting ice growth is then interpreted as a kind of **"potential icing"**.

The number of hours with **"active icing"** will then be given by number of hours having $dM/dt > 0.01 \text{ kg/m}$ with $D=0.03 \text{ m}$

Model domains: Scandinavia 9 km 2000-2011 with one turbulence and one cloud scheme (MYJ, WSM6) but with 3 different input for weather forcing.

GRAP 9KM

d01: 27 km
(Forced by FNL, NNRP or
ERA Interim)

d02: 9 km
(one way nested in d01)

Result: WRF-Scandinavia 9 km – no. of active icing hours

Annual averages 2000-2011, 3 different forcing.

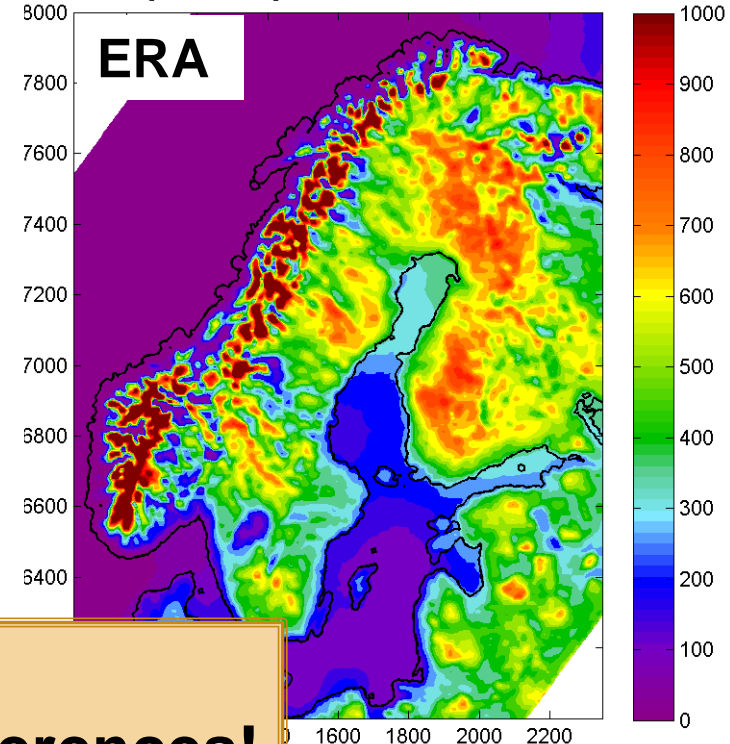

WRF - average annual icing hours 2000-2011 - 100 m - FNL

WRF - average annual icing hours 2000-2011 - 100 m - NNRP

WRF - average annual icing hours 2000-2011 - 100 m -ERA Interim

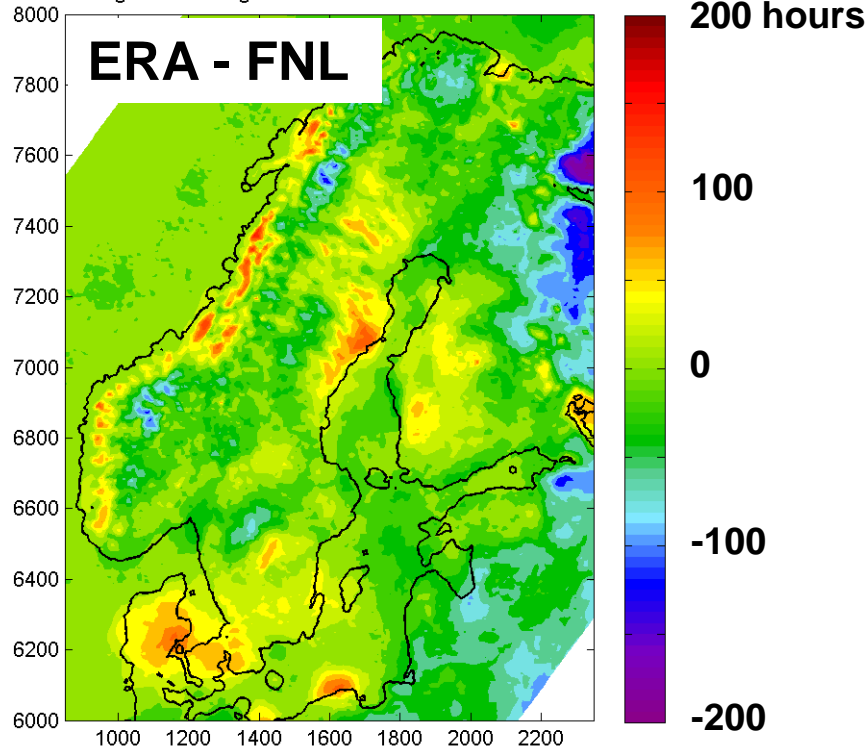

**Results are similar,
but with some regional differences!**

WRF - Scandinavia 9 km – number of active icing hours

Differences in annual averages 2000-2011 are typically ± 50 hours, but up to ± 200 hours

WRF - average annual icing hours 2000-2011 - 100 m - ERA Interim-FNL

WRF - average annual icing hours 2000-2011 - 100 m - NNRP-FNL

Model domains: Ryningsnäs 1 km, July 2011-June 2012 using 2 forcing sources, 3 turbulence and 2 cloud schemes.

WPS Domain Configuration

d01: 27 km

(Forced by FNL or ERA
Interim)

d02: 9 km

(one way nested in d01)

d03: 3 km

(one way nested in d02)

d04: 1 km

(one way nested in d03)

WRF – Ryningsnäs 1 km – icing hours winter 2011/12

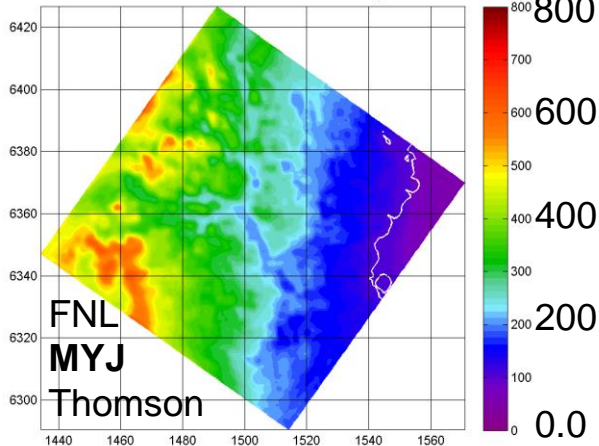

Same turbulence closure and cloud physics – different forcing.
Effect: ~25 % differences in number of icing hours.

WRF – Ryningsnäs 1 km – icing hours winter 2011/12

GRAP-1km-FNL MPH=Thomson PBL=MYJ - seasonal number of icing hours 2011/12 - 100 m

Same cloud physics and forcing – three different turbulence closures schemes. Effect: ~50 % differences in number of icing hours.

r/J - seasonal number of icing hours 2011/12 - 100 m

iRAP-1km-FNL MPH=Thomson PBL=MYNN - seasonal number of icing hours 2011/12 - 100 m

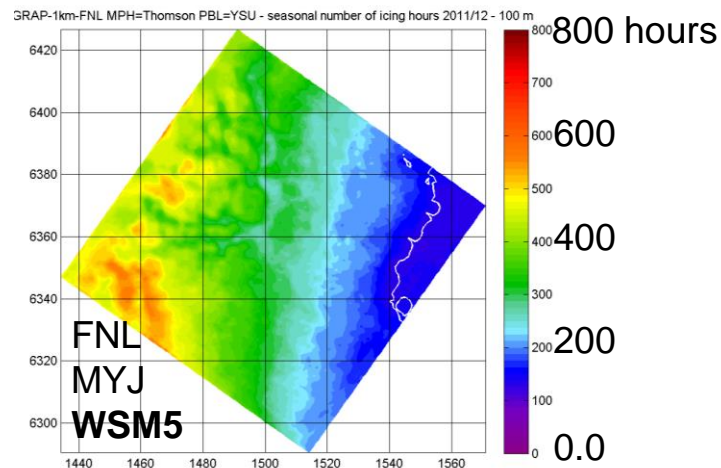

WRF – Ryningsnäs 1 km – icing hours winter 2011/12

Same turbulence scheme and forcing – two different cloud physics schemes.
Effect: ~25 % differences in number of icing hours.

WRF – Ryningsnäs 1 km – average wind speed 2011/12

Effects on wind speed:
Same cloud scheme and forcing – three different turbulence closures schemes. Differences up to ~0.5-1 m/s in annual average wind speed.

Different forcing sources and different cloud schemes of less importance.

WRF – Ryningsnäs 1 km – average LWC 2011/12

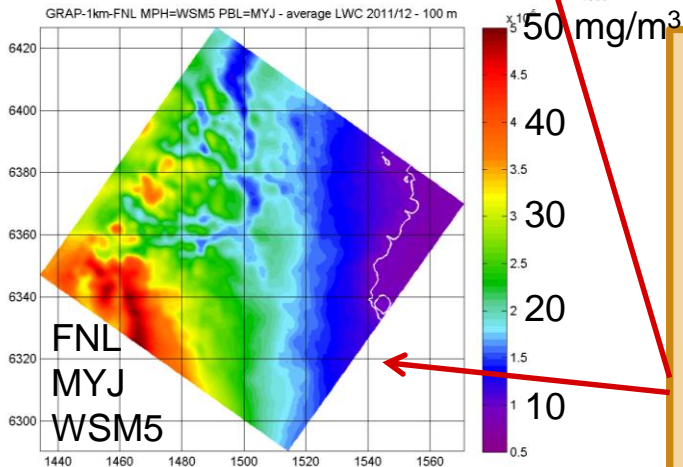

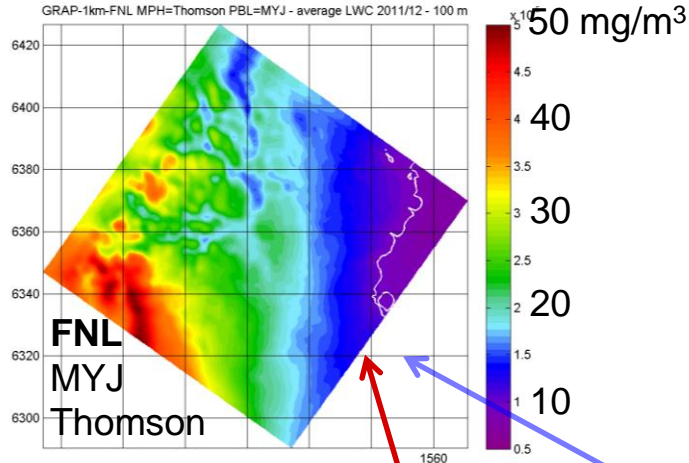

Effects on Liquid Water Content:
Same cloud scheme and forcing – three different turbulence closures schemes.
Differences up to ~ 25 mg/m³ in annual average LWC, ~ 50 % difference.

WRF – Ryningsnäs 1 km – average LWC 2011/12

Effects on Liquid Water Content:
Same turbulence and cloud scheme –
different forcing.
Differences up to ~ 15 mg/m³ in annual
average LWC.
Using different cloud physics gave
smaller differences in average LWC.

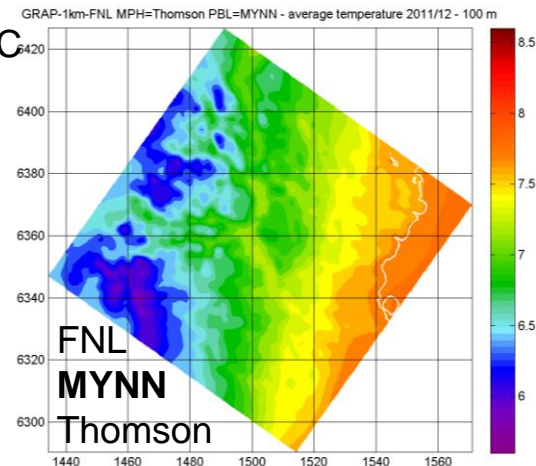

WRF – Ryningsnäs 1 km – average temperature 2011/12

Effects on temperature:

Same cloud scheme and forcing – three different turbulence closures schemes. Differences up to $\sim 0.3^{\circ}\text{C}$ in annual average temperature.

Different forcing sources and different cloud schemes of less importance.

Conclusions

- It definitely matters which WRF we use!
- The difference in number of active icing hours was found to be up to:
 - ~50 % due to choice of turbulence scheme
 - ~25 % due to choice of cloud physics scheme
 - ~10-20 % due to choice of forcing data
- Our preliminary findings indicate that FNL and ERA Interim give quite similar results, while NNRP deviates somewhat more.
- Typical differences due to choice of turbulence and cloud physics closure, and to choice of forcing data:
 - For annual hours with active icing $\sim \pm 200$ hours
 - For average wind speed ~ 1 m/s
 - For average temperature $\sim 0.3^\circ\text{C}$
